

Supplementary Materials

Supplementary Methods

Sampling: Specimens were collected using pit-trapping methods (Goodman & Ingle, 1993) with 28×30 cm (diameter×height) traps, which were inspected twice a day. The sampling areas were located in forest and forest edge shrub of the Dabie Mountains (1 064–1 273 m above sea level), Anhui Province, China.

Phylogenetic analyses: DNA was extracted from livers and muscles of the four samples using the standard proteinase K/phenol-chloroform method. PCR analysis (Sambrook et al., 1989) was performed targeting sequences of a mitochondrial molecular marker (Cyt *b*) and three nuclear markers (phospholipase C beta 4 [*PLCB4*], recombination activating protein 1 [*RAG1*], and recombination activating protein 1 [*RAG2*]). The Cyt *b* gene was amplified with primers L14724-hk3 and H15915-hk3 (Irwin et al., 1991), *RAG1* was amplified using primers F1705 and R2951, *RAG2* was amplified using primers RAG2-F220 and RAG2, and *PLCB4* was amplified using primers PLCB4-F and PLCB4-R (Wan et al., 2013). The thermal cycling conditions of the genes in the PCR program are provided in Supplementary Table S1. PCR products were sequenced by specialized biological companies.

The obtained sequences were concatenated and edited using SeqMan (DNASTAR, Lasergene v7.1) (Swindell & Plasterer, 1997). The sequences were then aligned in MUSCLE (Edgar, 2004) and further examined in MEGA6 (Tamura et al., 2013). In the R package, the dist.dna function in APE was used to calculate the pairwise distance matrix from the DNA sequences (Paradis et al., 2004). The DNA sequences of 95 individuals of *Uropsilus* from the mountains of Southwest China were downloaded from the National Center for Biotechnology Information (NCBI) database (Supplementary Table S2). *Sorex araneus* (Soricidae) and *Talpa altaica* (Talpinae) were used as outgroups. Bayesian inference (BI) and maximum parsimony (MP) were used for phylogenetic analysis. BI analysis was performed in MRBAYES v3.1.2 (Ronquist & Huiskenbeck, 2003). The most suitable nucleotide substitution model was specified in MrModeltest v2.4 (Nylander, 2004). A cold chain and three incremental heated chains were used for the 1 000 000 Metropolis-coupled Markov chain Monte Carlo generations, with sampling every 100 generations, which allowed the replacement parameters to be changed independently between two genes; the branch length of each gene was then proportionally estimated. MP analysis was performed in PAUP v4.0a (Swofford, 2002), using 1 000 repeats to randomly added sequences and the tree-branch reconnection (TBR) exchange algorithm. The support rate was calculated using 1 000 bootstrap repeats.

Species delimitation: BEAST v1.10.4 (Suchard et al., 2018) was used to construct Bayesian trees and estimate the time of species differentiation. Analyses were performed using four loci (Cyt *b*, *RAG1*, *RAG2*, and *PLCB4*), General Time Reversible (GTR) substitution model, gamma+invariant sites heterogeneity model, uncorrelated exponential relaxed molecular clock model, and Birth-Death process tree prior (Drummond et al., 2012; Wan et al., 2018). Based on previous research, four calibrations were used for more accurate time estimates: (1) The earliest known member of the crown clade of Talpidae and Erinaceidae+Soricidae (Roca et al., 2004)

\sim 73 Ma was used as the split of the most recent common ancestor (MRCA). We set the prior using lognormal distribution, such that the mean age was at 73 Ma (Roca et al., 2004). (2) The ancestor of Talpidae was from the Paleocene/Eocene boundary \sim 47 Ma (He et al., 2017) and we set the prior using normal distribution (mean=47, standard deviation=6.08). (3) The ancestors of *Uropsilus* first appeared in the Late Miocene; the prior was set using normal distribution (mean=6.18, standard deviation=1.5); therefore, the mean age was set to 6.18 Ma and the 95% upper boundary was set to 8.65 Ma (Wan et al., 2013). (4) The earliest known *U. soricipes* is from the Early Pleistocene 2.0–2.4 Ma; thus, the prior was set with a lower boundary of 2.0 Ma (offset=2.0, mean=0.67) and higher boundary of 2.38 Ma (Agustí et al., 2001). After BEAST analysis, Trace v1.6 (Rambaut & Drummond, 2010) confirmed that all effective sample sizes (ESSs) were greater than 200.

We used the Bayesian Poisson tree processes (bPTP) model to infer species boundaries in the concatenated phylogenetic tree (Zhang et al., 2013). As mitochondrial genes have a higher evolution rate than nuclear genes and the effective population of the present study was insignificant (Springer et al., 2001), mitochondrial genes were not used for analysis with the BPP v3.4 program (Yang & Rannala, 2010). This is because genetic infiltration and selection may have an effect; therefore, only sequences of the three nuclear markers were used in this analysis. Based on the Splits results, the specimens were divided into 23 polyphyletic taxa and analyzed using guided tree delimitation. The tree derived from BEAST was used as the guide tree. Analysis was performed using fixed-guide tree (A10) and non-guide tree (A11) species delimitation to avoid mixing problems (Yang, 2015). Species delimitation algorithms 0 and 1 were used for A10 and A11 species delimitation, respectively. Analysis was repeated 12 times for each dataset. Each rjMCMC was run for 1 000 000 generations, with sampling every 10 generations and 10 000 generations discarded as pre-burn-in. Automatic barcode gap discovery (Puillandre et al., 2012) was used to assess species boundaries. The JC69, K80, and “simple distance” models were selected for analysis using the ABGD Web server (<http://wwwabi.snv.jussieu.fr/public/abgd/abgdweb.html>), and the minimum gap width (X) of the agent was selected as 0.25 and 0.5 for analysis (Wan et al., 2018).

Morphological analyses: Morphometric measurements were obtained from the skulls of the four collected specimens and 23 other *Uropsilus* specimens with Vernier calipers to the nearest 0.01 mm (Table 1). The specimens belonged to five recognized species. The following measurements were obtained: profile length (PL), basal length (BL), greatest neurocranium breadth (GNB), zygomatic breadth (ZB), greatest breadth of snout (GBSn), least breadth between orbits (LBO), height of braincase (HB), median palatal length (MPL), length of mandibular tooth row including first incisor (LMTR), greatest width measured at anterior labial margins of second mandibular (M^2-M^2), and length of mandible not including first incisor (LM). These measurements refer to standards I and V of mammalian skull measurements (Liu et al., 2013; Yang et al., 2005, 2007). IBM SPSS Statistics 22.0 was used for independent-samples T test, principal component analysis (PCA), and discriminant function analysis (DFA) (Kirkpatrick & Feeney, 2014).
